## THE GREEN REVOLUTION: GLOBAL

- Paired introduction of high-yielding varieties (primarily rice, wheat) with increased irrigation and modern inputs
  - Early period 1961-1980, later period 1980-2000.
- Higher yields, intensification *and* land expansion, lower grain prices, decreased mortality and fertility rates, increased life expectancy, smaller populations, increased per capita GDP, increased non-ag labor productivity after a decade (Evenson & Gollin 2003; Gollin, Hansen, Windgender 2018; McArthur & McCord 2017)

• Surprising lack of focus on poverty, hunger, and inequality.

 GR meant to provide "a lasting solution" to the "perpetual problems of rural poverty and hunger," and to kickstart rural economies so as to "improve the quality of life at the grassroots in an appreciable measure" (Dhanagare 1987)

  - GR meant to provide "a lasting solution" to the "perpetual problems of rural poverty and hunger," and to kickstart rural economies so as to "improve the quality of life at the grassroots in an appreciable measure" (Dhanagare 1987)

In fact, economists from the GR era in India<sup>\*</sup> were highly concerned with distributional consequences, writing:

- Smallest farmers failing to adopt HYVs, taking out more credit to do so, or profiting less from them
- Controversy over the impact of HYVs on ag wages
- Landlords converting tenants/sharecroppers into laborers, possibly eroding land reform
- Increased skewness in land, farming assets, rural welfare
   Dhanagare (1987): "[A]II available statistics indicate greater and greater immiseration and pauperisation as the green revolution technology package has spread in... India."

## WE ASK...

- Did the green revolution influence the distribution of agricultural land in rural India?
  - Yes. → increased number of marginal farms, increase in land share held by the smallest and largest farms, reduction in middle-sized farms.
- Did it increase rural economic inequality?
  - Yes. → increased inequality in productive assets, per capita income, female schooling — improvements at top of distribution with no change at bottom
- Through what mechanisms did these changes occur?

## LITERATURE AND CONTRIBUTION

#### Disparate literature links ag productivity to rural inequality.

- New ag technologies often differentially benefit richer farmers (Goldstein & Udry 2008; Foster & Rosenzweig 2010; Hess, Jaimovich, & Schundeln 2021)
- And their impact on wages varies (Bustos, Caprettini, and Ponticelli, 2016)
- Increased ag productivity may influence family structure and farm division (Foster and Rosenzweig, 2002; Bardhan et al., 2014)

 Increased ag productivity → demand for education, non-ag sector spill-overs under some conditions (Foster & Rosenzweig 2001, 2004; Moscona 2019; Bustos, Caprettini & Ponticelli 2016, Hornbeck & Keskin 201

We directly estimate the influence of a new ag technology on rural distribution of productive capital + rural income. *Seems that lack of non-ag sector spill-over trapped the poorest in low-profit ag, with accompanying welfare impacts.* 

## DISTRICT-LEVEL VDSA DATA

DATA

.00

District-level data on agricultural conditions from the Village Dynamics in South Asia (VDSA) panel collected by ICRISAT

DISTRIBUTIONAL RESULTS

A PROBLEM

MECHANISM GLANCE

- Covers 311 districts across nineteen states, 1966-2011.
- Tracks the 1966 districts by apportioning data from subsequently-created districts.
- Data on cropping patterns, input use, area under high yielding varieties, irrigated area, etc.
- Holds the number of / acreage under marginal (< 1ha), small (1-4 ha), medium (4-10 ha) and large (>10 ha) farms approx every 5 years.
- Critically, the VDSA begins in 1966, the year that HYVs were introduced to India.

Using the household-level, ag-focused ARIS-REDS (dropping Jammu and Kashmir) to explore mechanisms.

- **1971.** 4,527 households in 259 villages in 100 districts of 17 states. In theory, representative of India's rural population.
- **1982.** Tracked 3,135 households outside of Assam (28% attrition) if intact or under 1971 head. Splits/splinters eligible for refresh along with new HHs (1,767 HHs).
- **1999.** Tracked 1982 households outside of Jammu and Kashmir, including splits/splinters within the village: 6,202 HHs (19% attrition). Refresh sampled new HHs only (1,271 HHs).
- Listing data

## NATIONAL FAMILY HEALTH SURVEY

Pooled individual-level maternal height and education data from two rounds of the National Family Health Survey (NFHS) conducted in 1998-1999 and 2015-2016.

- Nationally + urban/rural representative household surveys. 1998-99 representative at state level, 2015-2016 at district level.
- Maintain rural households only: 53,187 + 416,610 women
- Women 15-49 years old at time of survey. Women in the 2015/16 dataset born as early as 1965; women in the 1998/99 dataset as early as 1950.

MOTIVATION DATA **IDENTIFICATION** DISTRIBUTIONAL RESULTS A PROBLEM MECHANISM GLANCE

#### ID STRATEGY

How did the roll-out of HYVs impact the number of / land share held by marginal, small, medium-sized, or large farmers?

$$Num_{dt}^{k} = \phi_0 + \phi_1 HYV_{dt-1} + \phi_2 X_{dt-1} + \delta_d + \delta_{st} + \epsilon_{dt}$$

Number of / share of ag land owned by farmers of size *k* in district *d* in year *t*, *Share*<sup>*k*</sup><sub>*dt*</sub>. District-level prevalence of HYV adoption,  $HYV_{dt}$ , measured in share of gross cultivated land. District fixed effects  $\delta_d$ , state-year fixed effects  $\delta_{st}$ , and district-level concurrent and recent rainfall and temperature shocks,  $X_{dt}$ . MOTIVATION DATA **IDENTIFICATION** DISTRIBUTIONAL RESULTS A PROBLEM MECHANISM GLANCE

#### ID STRATEGY

How did the roll-out of HYVs impact the number of / land share held by marginal, small, medium-sized, or large farmers?

$$Num_{dt}^{k} = \phi_0 + \phi_1 HYV_{dt-1} + \phi_2 X_{dt-1} + \delta_d + \delta_{st} + \epsilon_{dt}$$

Number of / share of ag land owned by farmers of size *k* in district *d* in year *t*, *Share*<sup>*k*</sup><sub>*dt*</sub>. District-level prevalence of HYV adoption,  $HYV_{dt}$ , measured in share of gross cultivated land. District fixed effects  $\delta_d$ , state-year fixed effects  $\delta_{st}$ , and district-level concurrent and recent rainfall and temperature shocks,  $X_{dt}$ .

ID Strategy: While roll-out across states not random, we follow Bharadwaj et al. (2018) to claim that within a state-year, district-level variation is plausibly (mostly?) exogenous. We find supporting evidence — only rainfall/temp shocks are correlated with HYV roll-out, not socioeconomic characteristics.

MOTIVATION<br/>0000000DATA<br/>000IDENTIFICATION<br/>000000000DISTRIBUTIONAL RESULTS<br/>000000000A PROBLEM<br/>000000000MECHANISM GLANCE<br/>00000000

#### DID ROBUSTNESS CHECK

As a robustness check, we follow Sekhri & Shastry (2024) to examine how landholding patterns changed differentially over time in water-rich vs. water-scarce districts.

$$Num_{dt}^{k} = \zeta_0 + \Sigma_t \zeta_1^t A_d * t + \zeta_2 X_{dt-1} + \delta_d + \delta_t + \upsilon_{dt}$$

Each  $\zeta_1^t$  provides a year-specific change in the marginal effect of having thicker ( $\geq 100$  meters) aquifers ( $A_d = 1$ ), vis-a-vis the unidentified marginal effect in 1970.

If HYVs increases land inequality, marginal effect should increase for marginal and/or large farmers (i.e.,  $\zeta_1^t$  more positive over time) and decrease for medium-sized farmers (i.e.,  $\zeta_1^t$  more negative over time).

#### OTHER RURAL INEQUALITY OUTCOMES

I apply the original equation to rural distribution of productive farming assets, per capita income, female education levels.

$$Share_{dt}^{k} = \phi_0 + \phi_1 HYV_{dt-1} + \phi_2 X_{dt-1} + \delta_d + \delta_{st} + \epsilon_{dt}$$

Now, *Share*<sup>*k*</sup><sub>*dt*</sub> constructed from surveyed ARIS-REDS households within a district (*d*) and round (*t*), or from surveyed, rural NFHS women born in any given year (*t*) within a given district (*d*). I.e., share of surveyed households/ women in *d* and *t* falling within the 1st, 2nd, 3rd, or 4th (*k*th) income, height, or education quartile.

000000	000	000	00000000	00000000	000000

#### ROBUSTNESS

Results are similar if: we examine the roll-out of wheat HYVs and rice HYVs alone (rice slightly larger impact), we separate districts by aquifer thickness, we examine concurrent HYV prevalence or prevalence lagged by 5 years, or we use the 1970-1980, -1986, -1990, -1995, or entire 1970-2000 sample.
#### ROBUSTNESS

Results are similar if: we examine the roll-out of wheat HYVs and rice HYVs alone (rice slightly larger impact), we separate districts by aquifer thickness, we examine concurrent HYV prevalence or prevalence lagged by 5 years, or we use the 1970-1980, -1986, -1990, -1995, or entire 1970-2000 sample.

Results NOT driven by measurement error in 1990-2000 HYV acreage: results similar in the earlier data alone, when we dropping districts with more missing 1990-2000 data, and when we additionally drop likely-errored values. In fact, it seems like measurement error in HYV roll-out is biasing treatment effects towards zero, as it would if classical.

#### LAND VS. WELFARE

Livelihood diversification  $\rightarrow$  distribution of other productive assets or total household income "much less inequitous than land or farm income distribution" (Bhalla and Chadha, 1982b)?

Moreover, medium-sized farmers – perhaps particularly near towns – may be exiting agriculture for potentially lucrative non-farm opportunities (Rao, Eberhard, and Bharadwaj 2022).

▲ロト ▲帰 ト ▲ ヨ ト ▲ 目 目 の Q ()

So while some Indian economists at the time did warn of distributional welfare impacts, seems like it could go either way...

Observations	938	1647	902	269
Within R <sup>2</sup>	0.0130	0.0125	0.0194	0.0225

Outcome: Indicator for exiting the panel in 1982 or 1999.  $\Delta HYV_t$  provides the change in the proportion of gross cropped area dedicated to HYVs between 1971 and 1982 (1982 obs) or between 1982 and 1999 (1999 obs). Sample: ARIS-REDS panel and refresh households in 1982 and 1999 if in the base year (1971 or 1982, respectively) the household: was landless (col 1), owned agricultural land (col 2). In both columns 1982 households with a household head over 40 in 1971 were dropped, since these households are likely to have exited the panel due to dissolution rather than migration (Foster and Rosenzweig, 2002). District-clustered standard errors in parenthesis. \*\*\* p<0.01, \*\* p<0.05, \* p<0.1

#### ARIS-REDS DATA

- **1971.** Additional Rural Incomes Survey (ARIS): 4,527 households in 259 villages in 100 districts of 17 states. In theory, representative of India's rural population, oversampling villages with greater HYV uptake and wealthier (larger-farm) households. Weights provided.
- **1982.** Rural Economic and Demographic (REDS) survey: tracked 3,135 panel households outside of Assam. Tracked HHs if either intact or under 1971 head; split-offs not tracked.
  - Attrition (28%): '71 head died and the HH splintered, entire HH left village, HH refused/absent (rare).
  - Refresh (1,767 HHs): *did* sample spit-offs and splinter HHs + new households not in the 1968 listing data.
- **1999.** Tracked 1982 households outside of Jammu and Kashmir, including splits / splinter HHs residing in the same village: 6,202 HHs.
  - Attrition (19%): entire HH left village, HH refused/absent.
  - Refresh (1,271 HHs): new households not in the 1981 listing data.

- District strata: Intensive Agricultural Development Program (IADP), villages within the Intensive Agricultural Area Program (IAAP), and all other villages.
- Income strata: H (≥ Rs 6,000), M (Rs 3,600-6,000), L (< Rs 3,600). Approx 20 HHs selected per village, oversampling H- and M-income HHs such that no L-income HHs were sampled if > 20 H- and M-income HHs existed in village.
- In theory, provided 1971 weights should up-weight poorer households and down-weight richer households such that a nationally representative sample is obtained.
